RDAP Conformance Tool

ICANN 72 - TechDay

Eduardo Alvarez
ICANN

25 October 2021

ICANN org's RDAP Conformance tool

- A stand-alone, open-source tool to verify that an RDAP server implements the specifications developed by the IETF and optionally, the [gTLD RDAP profile](#).
 - Free.
 - Developed in Java 11.
 - Command line.
 - Flexible configuration to enable/disable specific checks as needed.

	Test groups	Tests
RDAP Standards/RFCs	27	212
gTLD RDAP Profile 2019	11	74

Conformance tests

- Tests are the atomic unit of processing of the tool
- Identified with a “code”, “value” and “message”
- Aggregated in test groups

Example:

7.2.1. RDAP Conformance validation [stdRdapConformanceValidation]

The following steps should be used to test that an *RDAP Conformance* data structure is valid:

1. The *RDAP Conformance* data structure must be a syntactically valid JSON array.

```
{  
    "code": -10500, } Test identifier (Error code)  
    "value": "<rdapConformance structure>",  
    "message": "The RDAP Conformance structure is not syntactically valid."  
}
```

2. ...

Supported RDAP query types

1

Domain lookup

..../domain/<domain name>

2

Entity lookup

..../entity/<handle>

3

Nameserver lookup

..../nameserver/<nameserver name>

4

Nameserver search

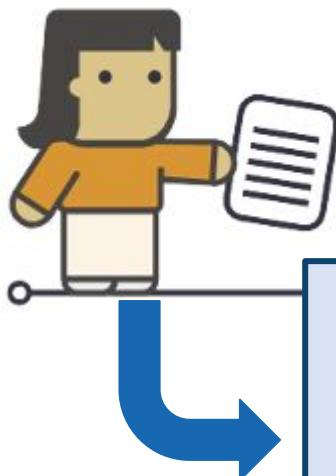

..../nameservers?ip=<nameserver search pattern>

5

Help query

..../help

Tool workflow

User Input

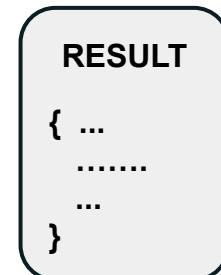

- Configuration file
- Execution parameters
- RDAP URI

RDAP CONFORMANCE TOOL

- Retrieve public datasets from IANA
- Perform RDAP query(ies)
- Verify response against RDAP standards
(RFC 7480-7484, 8605, 9082, 9083)
- Optionally gTLD RDAP profile

Output

- Results file

User input

- **Configuration definition file**
 - Specify which single tests are considered to be:
 - Error (default)
 - Warning
 - Ignored (not tested)
 - **Execution parameters**
 - Use gTLD RDAP profile 2019
 - As gTLD Registry
 - As gTLD Registrar
 - Verify as “thin” Registry
 - Use locally persisted datasets
 - Connection timeout
 - **RDAP URI**
 - The full RDAP URI to verify
-

Output

Results file

- JSON formatted text file, includes:
 - Tested URI
 - Tested date
 - Received HTTP status code
 - Test groups that passed
 - Test groups that had errors or warnings
 - Results
 - Each test triggering an error or warning is listed in an array of JSON objects that contain failing test identifier:
 - **code**: a JSON number containing the test identifier.
 - **value**: a JSON string where the issue was found.
 - **message**: a JSON string explaining the issue.
 - **notes**: a JSON string containing the notes defined in the configuration definition file.

Sample output

```
{  
    "testedDate": "2021-09-22T07:30:27.561327Z",  
    "groupOK": [  
        "stdRdapDomainLookupValidation",  
        "domainNameValidation",  
        ...  
    ],  
    "definitionIdentifier": "My custom configuration for checking RDAP",  
    "groupErrorWarning": [  
        "stdRdapEventsValidation"  
    ],  
    "results": {  
        "warning": [],  
        "ignore": [],  
        "error": [  
            {  
                "code": -10901,  
                "notes": "",  
                "message": "The name in the name/value pair is not of: eventAction,  
                           eventActor, eventDate, links.",  
                "value": "#/nameservers/0/events/0/extra:I do not belong here"  
            }  
        ]  
    },  
    "testedURI": "https://rdap.example/domain/domain.example",  
    "receivedHttpStatusCode": 200  
}
```

“groupOK” lists check groups without issues

Each non-conformant issue is added as an “error” object

Commonly found issues

Seen on TLD servers published in the [IANA bootstrap file for DNS registrations](#).

- Vcard array syntax issues in entity objects:
 - Use of invalid JSON names
 - Missing required elements (e.g. “fn”)
 - Invalid value syntax (e.g. invalid URI)
- Use of values not registered in the [RDAP JSON values](#) IANA registry.
For example:
 - type
 - status
 - eventAction
- Incorrect capitalization used in JSON names.

Commonly found issues

- rdapConformance includes extensions not registered in the [RDAP Extensions](#) IANA registry.
 - Invalid “remarks”/“notices” array (e.g. missing elements).
 - Missing HTTP header (Access-Control-Allow-Origin).
 - “links” type does not correspond to a registered mediaType.
 - Unrecognized elements included in dsData element.
-

Future work

- Publish open source tool
 - Additional development:
 - Support for JSContact ([draft-ietf-jmap-jscontact](#))
 - Support future versions of the gTLD RDAP Profile
 - Evaluating incorporating other RDAP extensions and RFC updates
-

Thank You and Questions

Comments and questions are welcome at our public mailing list:
